

WEBX Module 2

Differentiate between CMS and Framework

A Content Management System (CMS) is a ready-to-use application for creating, managing, and publishing digital content without coding. A Framework is a foundational code library that developers use to build custom applications from scratch.

Feature	CMS	Framework
User	Non-technical users	Developers only
Speed	Fast setup	Slower development
Control	Limited by plugins	Full control
Examples	WordPress, Joomla	Laravel, Django

What is Content Management System (CMS)?

A CMS is software that allows users to create, edit, organize, and publish web content through a graphical interface, requiring no HTML or programming knowledge. It separates content management (backend) from presentation (frontend).

Features:

- WYSIWYG
- Editors
- User role management
- Version control
- Templates
- Plugin extensions

Popular examples are WordPress, Joomla, and Drupal.

Explain Drupal's architecture with its advantages

Drupal is built on a modular, hook-based architecture using Symfony components. Core elements include: Nodes (content units), Taxonomy (categorization), Modules (extend functionality), Themes (presentation), and Hooks (allow modules to interact with core events).

Advantage	Description
Security	Enterprise-grade, regular advisories
Scalability	Handles millions of nodes, high traffic
Flexibility	Custom content types and workflows
Multilingual	Built-in translation

State the advantages and disadvantages of Joomla

Advantages	Disadvantages
User-friendly backend for non-developers	Fewer free extensions than WordPress
Strong access control levels (ACL)	Steeper learning curve than WordPress
Built-in multilingual support (no plugins)	Less flexible for complex custom post types
Balanced for e-commerce and social networking	Smaller community than WordPress or Drupal
Decent performance and caching	Updates may break extensions or layouts

Joomla suits community portals, e-commerce, and corporate websites but may require developer help for advanced features.
